(57) **ABSTRACT**

A system or method selects among multiple tuners to tune a
particular channel. A request is received to tune a first chan-
nel. In response to this request, a first tuner is assigned to tune
the first channel. A request is received to tune a second chan-
nel. If the program tuned by the first tuner is not being
recorded, the first tuner is assigned to tune the second chan-
nel. If the program tuned by the first tuner is being recorded,
the second tuner is assigned to tune the second channel.

METHOD AND APPARATUS FOR SELECTING AMONG MULTIPLE TUNERS

RELATED APPLICATIONS

This application is a Continuation of, and claims priority to, U.S. patent application Ser. No. 11/171,875, filed Jun. 30, 2005, entitled "Method and Apparatus for Selecting Among Multiple Tuners", now U.S. Pat. No. 7,701,516, which is a continuation of U.S. patent application Ser. No. 10/997,423, filed Nov. 24, 2004, entitled "Method and Apparatus for Selecting Among Multiple Tuners", now U.S. Pat. No. 7,277,137, which is a continuation of U.S. patent application Ser. No. 10/039,225 file Jan. 4, 2002, entitled "Method and Apparatus for Selecting Among Multiple Tuners", now U.S. Pat. No. 6,897,904, all of which are incorporated herein by reference.

TECHNICAL FIELD

This invention relates to selecting among multiple tuners to tune a particular channel.

BACKGROUND OF THE INVENTION

Existing televisions, set top boxes, and other devices that tune broadcast signals contain a single tuner which is capable of tuning one of several different channels contained in a broadcast signal. Since these existing device contain a single tuner, they are not capable of tuning two or more different channels simultaneously (without the help of an external tuning device). Thus, when a user submits a request to change channels, the single tuner is instructed to change to the requested channel. Since there is only one tuner, there is no question as to which tuner will tune the requested channel.

However, with the development of televisions, set top boxes, and other client devices that contain multiple tuners, issues arise regarding which tuner should be used to tune a particular channel when a request to change channels is received. For example, once a particular tuner begins tuning and recording a program, that tuner cannot be used to tune any other channel without stopping the recording process. If a request to change channels is received while a particular channel is being recorded, the system must determine whether the user desires to stop the recording and view the new channel or to continue recording the previous channel while viewing the new channel. Repeatedly prompting the user to select a tuner to tune a particular channel is likely to be frustrating and distracting to the user.

Therefore it is desirable to provide a system that selects among multiple tuners to tune a particular channel in a manner that is least intrusive to the user of the system.

SUMMARY OF THE INVENTION

The systems and methods described herein select among multiple tuners to tune a requested channel. These systems and methods require little or no input from the user as to which tuner should be assigned to tune a particular channel. For example, if a new channel is selected by the user and a tuner is available to tune the new channel, the available tuner is automatically assigned to tune the new channel without requiring any user input or otherwise disrupting the channel selection process.

In a particular embodiment, a request is received to tune a first channel. A first tuner is assigned to tune the first channel. Another request is received to tune a second channel. The first

2

tuner is assigned to tune the second channel if the program tuned by the first tuner is not being recorded. The second tuner is assigned to tune the second channel if the program tuned by the first tuner is being recorded.

Another embodiment receives a request to record a program on a first channel. A first tuner is assigned to tune the first channel. Another request is received to tune a second channel. A determination is made regarding whether the second channel is already being tuned. Another determination is made regarding whether a second tuner is available for tuning. The first tuner is assigned to tune the second channel if the second channel is not already being tuned and the second tuner is not available for tuning. The second tuner is assigned to tune the second channel if the second channel is not already being tuned and the second tuner is available for tuning.

According to one aspect of the invention, the system switches to the tuner assigned to the second channel if the second channel is already being tuned.

BRIEF DESCRIPTION OF THE DRAWINGS

The same reference numerals are used throughout the drawings to reference like components and features.

FIG. 1 illustrates an exemplary environment in which the methods and systems described herein may be implemented.

FIG. 2 is a block diagram of an example client device, a television, and various input devices that interact with the client device.

FIG. 3 is a block diagram of selected components of the client device shown in FIGS. 1 and 2.

FIG. 4 is a block diagram of an exemplary client device that includes two tuners, a tuner controller, a disk drive, and a pair of decoders.

FIG. 5 is a flow diagram illustrating an embodiment of a procedure for determining which tuner to use when a user selects a new channel to view.

FIG. 6 is a flow diagram illustrating an embodiment of a procedure for determining which tuner to use when one tuner is recording a program and a change channel command is received.

DETAILED DESCRIPTION

FIG. 1 illustrates an exemplary environment 100 in which the methods and systems described herein may be implemented. One or more content providers 102 include stored content 118 and a content server 120. Content server 120 controls the movement of content (including stored content 118) from the content provider 102 to a content distribution system 104, which is coupled to the content provider. Additionally, the content server 120 controls the movement of live content (e.g., content that was not previously stored by the content provider) and content stored at other locations to the content distribution system.

The content distribution system 104 contains a broadcast transmitter 122 and one or more content processors 124. Broadcast transmitter 122 broadcasts signals (e.g., cable television signals) across a broadcast network 116, such as a cable television network. Broadcast network 116 may include wired or wireless media using any broadcast format or broadcast protocol. Content processor 124 processes the content received from content provider 102 prior to transmitting the content across the broadcast network 116. A particular content processor may encode or otherwise process the received content into a format that is understood by multiple client devices 106 coupled to the broadcast network 116. Although FIG. 1 shows a single content provider 102 and a single

3

content distribution system **104**, a particular environment may include any number of content providers coupled to any number of content distribution systems.

A client device **106(1)** receives broadcast content from a satellite-based transmitter via a satellite dish **110**. Client device **106(1)** is also referred to as a set-top box, game console or a satellite receiving device. Client device **106(1)** is coupled to a television **108(1)** for presenting the content received by the client device (i.e., audio data and video data) as well as a graphical user interface. A particular client device **106** may be coupled to any number of televisions **108**. Similarly, any number of client devices **106** may be coupled to a television **108**. Another client device **106(2)** is coupled to receive broadcast content from broadcast network **116** and provide the received content to a television **108(2)**. Another client device **106(N)** is a combination of a television **112** and a set-top box **114**. In this example, the various components and functionality of the set-top box are incorporated into the television, rather than using two separate devices. The set-top box incorporated into the television may receive broadcast signals via a satellite dish (similar to satellite dish **110**) and/or via broadcast network **116**. In alternate embodiments, client devices **106** may receive broadcast signals via the Internet or any other broadcast medium.

FIG. 2 is a block diagram of an example client device **106**, television **108**, and various input devices that interact with the client device. As discussed above, client device **106** may also be referred to as a set-top box, a game console or a satellite receiver. Client device **106** includes a wireless receiving port **202** (e.g., an infrared (IR) wireless port) for receiving wireless communications from a remote control device **204**, a handheld device **206** (such as a personal digital assistant (PDA) or handheld computer), or other wireless device, such as a wireless keyboard. Additionally, a wired keyboard **208** is coupled to client device **106** for communicating with the client device. In alternate embodiments, remote control device **204**, handheld device **206**, and/or keyboard **208** may use an RF communication link (or other mode of transmission) to communicate with client device **106**.

Client device **106** receives one or more broadcast signals **220** from one or more broadcast sources (e.g., from a broadcast network or via satellite). Client device **106** includes hardware and/or software for receiving and decoding broadcast signal **220**, such as an NTSC, PAL, SECAM or other TV system video signal, and providing video data to the television **108**. Client device **106** also includes hardware and/or software for providing the user with a graphical user interface by which the user can, for example, access various network services, configure the client device **106**, and perform other functions.

Client device **106** receives AC power on line **110**. Client device **106** is capable of communicating with other devices via a conventional telephone link **212**, an ISDN link **214**, a cable link **216**, and an Ethernet link **218**. A particular client device **106** may use any one or more of the various communication links **212-218** at a particular instant. Client device **106** also generates a video signal and an audio signal, both of which are communicated to television **108**. The video signals and audio signals can be communicated from client device **106** to television **108** via an RF (radio frequency) link, S-video link, composite video link, component video link, or other communication link. Although not shown in FIG. 2, a particular client device **106** may include one or more lights or other indicators identifying the current status of the client device. Additionally, a particular client device **106** may include one or more control buttons or switches (not shown) for controlling operation of the client device.

4

FIG. 3 is a block diagram of selected components of the client device **106** shown in FIGS. 1 and 2. Client device **106** includes multiple tuners **300** and **302**, one or more processors **304**, a random access memory (RAM) **306**, and a non-volatile memory **308** that contains, for example, an operating system **310** and one or more application programs **312**. Client device **106** also includes a disk drive **314** and storage media **316**. Although client device **106** is illustrated having both a RAM **306** and a disk drive **314**, a particular device may include only one of the memory components. Additionally, although not shown, a system bus typically couples together the various components within client device **106**.

Processor(s) **304** process various instructions to control the operation of client device **106** and to communicate with other electronic and computing devices. The memory components (e.g., RAM **306**, disk drive **314**, storage media **316**, and non-volatile memory **308**) store various information and/or data such as configuration information and graphical user interface information.

Client device **106** also includes a decoder **318**, such as an MPEG-2 decoder that decodes MPEG-2-encoded signals. A modem **320** allows client device **106** to communicate with other devices via a conventional telephone line. An IR interface **322** allows client device **106** to receive input commands and other information from a user-operated device, such as a remote control device or an IR keyboard. Client device **106** also includes a network interface **324**, a serial/parallel interface **326**, an audio output **328**, and a video output **330**. Interfaces **324** and **326** allow the client device **106** to interact with other devices via various communication links. Although not shown, client device **106** may also include other types of data communication interfaces to interact with other devices. Audio output **328** and video output **330** provide signals to a television or other device that processes and/or presents the audio and video data. Although client **106** is illustrated having multiple interfaces, a particular client may only include one or two such interfaces.

Client device **106** also includes a user interface (not shown) that allows a user to interact with the client device. The user interface may include indicators and/or a series of buttons, switches, or other selectable controls that are manipulated by a user of the client device.

General reference is made herein to one or more client devices, such as client device **106**. As used herein, "client device" means any electronic device having data communications, data storage capabilities, and/or functions to process signals, such as broadcast signals, received from any of a number of different sources.

FIG. 4 is a block diagram of a portion of an exemplary client device that includes two tuners, a tuner controller, a disk drive, and a pair of decoders. The exemplary client device contains additional components (such as those shown in FIG. 3) which are omitted from FIG. 4 to simplify discussion of specific components. A pair of tuners **402** and **404** each receive broadcast signals from a one or more broadcast sources. Certain broadcast signals may include encoded data, such as encoded video data and encoded audio data. In this situation, a decoder is used to decode the encoded data.

In a particular embodiment, the broadcast signals include data encoded using the MPEG-2 (Moving Pictures Experts Group) encoding format. MPEG-2 is a standard for digital video and digital audio compression. MPEG-2 supports a variety of audio/video formats, including legacy TV, HDTV (High-Definition Television), and five channel surround sound. However, the methods and systems described herein can be used with any type of signal using any type of encoding format as well as signals that do not use any encoding.

5

Referring again to FIG. 4, each tuner 402 and 404 maintains an internal “state”. This state information may include, for example, the channel currently being tuned (if any) and whether the tuner is creating a pause buffer (e.g., for “pausing” a live broadcast) or creating an archival recording of the program. Each tuner 402 and 404 is coupled to a tuner controller 406. Tuner controller 406 receives user control inputs, such as a user request to change channels or record a program being broadcast on a particular channel. These user control inputs may be provided through a remote control device, wireless keyboard, or other input device. Tuner controller 406 processes the received user control inputs and sends control instructions, if necessary, to tuner 402 and/or tuner 404. For example, if the user requests to change from viewing channel 204 to channel 206, the tuner controller 406 instructs one of the tuners 402 or 404 to begin tuning channel 206. Additionally, tuners 402 and 404 can communicate information to tuner controller 406, such as the current channel being tuned by the tuner. Although two tuners are illustrated in FIG. 4, a particular implementation may contain any number of tuners.

A disk drive 408 is coupled to tuners 402 and 404, tuner controller 406, and a pair of decoders 410 and 412. Disk drive 408 is capable of storing program data received from tuner 402 and/or 404 and replaying that program data at a later time. Tuner controller 406 controls the recording of programs by sending appropriate commands to disk drive 408. Disk drive 408 may also store other information used by the client device such as configuration information. Disk drive 408 outputs encoded program content to decoder 410 and/or 412. The decoder 410, 412 then decodes the encoded program content and outputs decoded signals, such as decoded video signals and decoded audio signals. Tuners 402 and 404 are also coupled to decoders 410 and 412 and may provide tuned signals directly to decoder 410, 412 if the tuned signal is being watched live (i.e., not being played back from the disk drive 408). Although FIG. 4 illustrates two decoders 410 and 412, alternate embodiments include a single decoder that decodes signals from both tuners 402 and 404, or from disk drive 408.

Alternatively, disk drive 408 may output signals directly (i.e., not through decoder 410, 412) if the program content stored on the disk drive does not require decoding. Similarly, tuners 402, 404 may output signals directly if the program content being tuned does not require decoding.

FIG. 5 is a flow diagram illustrating an embodiment of a procedure 500 for determining which tuner to use when a user selects a new channel to view. Initially, a user selects a channel to view (block 502). A first tuner is assigned to tune the channel selected by the user (block 504). The user then selects a new channel to view (block 506). The procedure 500 then determines whether the program being tuned by the first tuner is being recorded (block 508). This determination can be performed by querying the state of the first tuner to determine whether the program is being recorded. If the program being tuned by the first tuner is not being recorded, the procedure assigns the first tuner to tune the new channel (block 510). If the program being tuned by the first tuner is being recorded, the procedure assigns a second tuner to tune the new channel (block 512). The manner in which a tuner is selected for the new channel minimizes disruption to the user of the client device. For example, if the client device is already recording a program on one channel, that recording is not disturbed by the user's request to view a different channel. Instead of changing the channel assigned to the tuner that is tuning the recorded channel, a second tuner is used to tune the new channel.

6

FIG. 6 is a flow diagram illustrating an embodiment of a procedure 600 for determining which tuner to use when one tuner is recording a program and a change channel command is received. Initially, a user selects a channel to record (block 602). A first tuner is assigned to tune the selected channel (block 604). The user then selects a new channel to view (block 606). The procedure 600 then determines whether the new channel is already being tuned by another tuner (block 606). If the new channel is already being tuned by another tuner, then block 610 of the procedure switches to the tuner assigned to the new channel (i.e., the new “active” tuner is the tuner that was already tuning the newly selected channel). The procedure then awaits the next user input (block 618). If the “new channel” was being recorded, the user is provided with a graphical indication on the television screen and/or an audible sound indicating that the program is being recorded.

By checking to see if the requested channel is already being tuned by another tuner, the system maintains the highest number of available tuners and avoids the situation where one tuner is recording a program from a particular channel and another tuner is being used to tune and display the program from the same channel. Also, by switching back to a tuner that is tuning and recording the requested channel, the user has access to the previously recorded program content. Certain systems empty the “pause buffer” (i.e., recorded portions of the program) in response to a channel change. If a new tuner was used to tune and display the selected channel, the previously recorded portions of the program would not be available to the user. However, by switching control to the tuner already recording the content, the user has access to the recorded content.

When switching back to a channel that is being recorded, the system can begin displaying the program content currently being tuned by the tuner. Alternatively, the system can begin displaying previously recorded program content, such as playing back the recorded program starting at the beginning of the program or playing back the recorded program from the point at which the user previously changed channels (i.e., switched away from the recorded program).

Referring again to FIG. 6, if the new channel selected at block 606 is not already being tuned by another tuner, the procedure 600 determines whether a second tuner is “available” for tuning the new channel (block 612). An “available” tuner as used herein may be defined in several different ways. An “available” tuner may be idle or may be engaged in a task that has a lower priority than the priority of allowing a user to change a channel being viewed. For example, using the tuner to receive non-urgent data may be a lower priority than changing a viewed channel, but using the tuner to record a second program may be a higher priority than changing a viewed channel. One tuner can determine whether another tuner is available by querying the other tuner to determine its status and priority.

If a second tuner is not available for tuning the new channel, then the procedure changes the first tuner to the new channel (block 614). The procedure then awaits the next user input (block 618). If a second tuner is available for tuning the new channel, then the procedure assigns the second tuner to the new channel (block 616). The procedure then awaits the next user input (block 618).

In a particular embodiment, recorded program content is associated with the tuner that originally tuned the recorded program. When a first tuner is tuning program content that is being recorded and a problem occurs with the first tuner or a higher priority task is assigned to the first tuner, a new tuner is selected to tune the program. In this situation, the recorded program content may be changed such that the recorded pro-

gram content is associated with the new tuner. Thus, the user is still able to view the previously recorded program content (tuned by the first tuner) even though the first tuner is no longer available. For example, if the first tuner malfunctions or the signal line providing broadcast signals to the first tuner is damaged, the tuning operation is switched to a second tuner and the previously recorded program content is modified to be associated with the new tuner. Alternatively, the program content tuned by the second tuner may be stored as a separate file that is "linked" to the previously recorded program content. By linking the two files, the user is able to easily access the entire recorded program content even though the program content is saved in two different files.

In one embodiment, one or more user interface features are provided that indicate to the user that, upon switching back to a channel that is being recorded, the user is now watching a recorded show. This indication reassures the user that their recording is proceeding properly. This indication also reminds the user that they have the ability to access previously recorded portions of the program, if desired.

Portions of the systems and methods described herein may be implemented in hardware or a combination of hardware, software, and/or firmware. For example, one or more application specific integrated circuits (ASICs) or programmable logic devices (PLDs) could be designed or programmed to implement one or more portions of the systems and procedures described herein.

Although the invention has been described in language specific to structural features and/or methodological steps, it is to be understood that the invention defined in the appended claims is not necessarily limited to the specific features or steps described. Rather, the specific features and steps are disclosed as preferred forms of implementing the claimed invention.

The invention claimed is:

1. A method performed by a set top box comprising:
receiving a request to tune to a first channel;
assigning a first tuner to tune the first channel;
receiving a request to tune to a second channel;
querying the first tuner to determine if the first tuner is recording the first channel;
if the first tuner is not recording the first channel, assigning the first tuner to the second channel; and
if the first tuner is recording the first channel, assigning a second tuner to tune the second channel.
2. The method as recited in claim 1, wherein the step of assigning the second tuner to tune to the second channel is based on a priority of the request to tune to the second channel.

3. The method as recited in claim 1, further comprising if the first tuner is recording and the second tuner is not available, assigning a third tuner to tune to the second channel.

4. The method as recited in claim 3, wherein the second channel is not available when the second tuner is recording a third channel.

5. One or more computer-readable media not consisting of a propagated data signal, the one or more computer-readable media having stored thereon a computer program that, when executed by one or more processors, causes the one or more processors to perform operations comprising:

- receiving a request to tune a first channel;
- assigning a first tuner to tune the first channel;
- receiving a request to tune a second channel;
- executing a query on the first tuner to determine tuner availability;
- assigning the first tuner to tune the second channel if the first channel is not currently being recorded; and
- executing a query on a second tuner; and
- assigning the second tuner to tune the second channel if the first channel is currently being recorded and the second tuner is available.

6. The one or more computer readable media as recited in claim 5, the operations further comprising maintaining a status of the first tuner such that if the first tuner is tuned to a channel that is currently being recorded, the status of the first tuner indicates that the first tuner is unavailable.

7. The one or more computer-readable media as recited in claim 5, wherein the operations further comprise the step of recording the second channel on the second tuner; and

- changing a status of the second tuner to a not available state.

8. The one or more computer-readable media as recited in claim 5, the operations further comprising assigning the second tuner to tune the first channel if the first tuner is not available to tune the first channel.

9. The one or more computer-readable media as recited in claim 8, the operations further comprising modifying a set of recorded program data associated with the first tuner to be associated with the second tuner if the first tuner is not available to tune the first channel.

10. The one or more computer-readable media as recited in claim 8, the operations further comprising generating a new set of recorded program data and associating the new set of recorded program data with the second tuner.

- 11. The method of claim 1, further comprising:
receiving a subsequent request to tune the first channel;
switching to the first tuner; and
displaying an indicator that the user is now watching a recorded program.
